CLIMATE NOTE

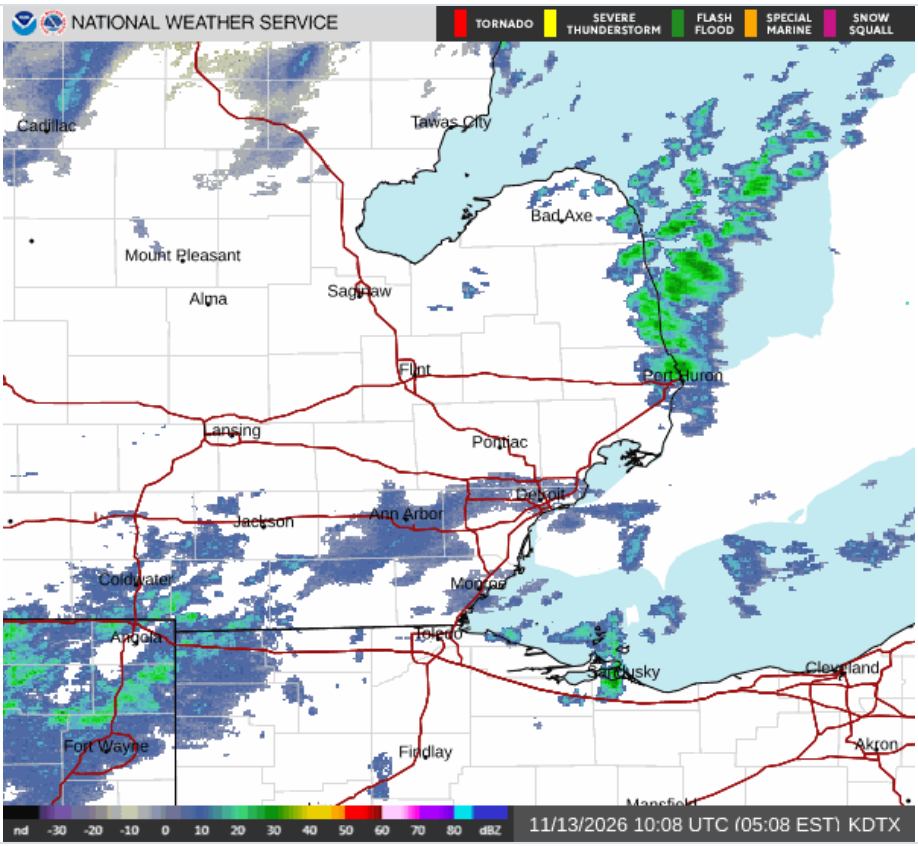

NOTE

A highly amplified omega pattern has settled in over the entirety of CONUS this morning, with Southeast Michigan positioned within the eastern longwave trough axis. The primary vicinity upper low eventually centers over Pennsylvania today, but its cyclonic wind field will preserve northerly flow throughout the day. This dislodges a pocket of colder Canadian air across the broader Great Lakes region, marked by 850 mb temperatures of 5 to 10 C below zero. Latest Lake Huron water temperatures are estimated around 10C, yielding a delta of 15-20C. In combination with favorable fetch, over lake instability supports the continuation of lake effect showers through the morning hours, with an expansion in coverage likely. Forecast soundings still support a wide range of precipitation outcomes given the underlying thermodynamics. The most likely time-frame for snow to mix in or become established as the dominant precipitation type is more likely to occur between 09Z and 15Z when the boundary-layer could support a nearly frozen parcel path. The main limiting factor that could favor more persistence for rainfall is the subtle backing of 850 mb/7 kft winds toward the NNW, introducing a disruptive drying component at the top of the saturation layer and the bottom of the DGZ. As for model trends, local probabilistic guidance and the NBM have steeply declined in the spatial coverage of accumulating snow. Additionally, the areas that could see some accumulations, are now expected to be more limited, mainly downstream of The Thumb, and along the immediate southern Lake Huron shoreline. This requires more resilient convergence bands to persist, and then reorient with the subtle backing of controlling lower column flow. A survey of recent observations show a lag in cooling/drying which kept dewpoints above freezing for many locations into the early morning hours. At press time, no observing equipment were reporting snowfall. The sites to keep an eye on for today should be KCFS, KBAX, and KPHN. Should DGZ saturation, wet-bulb cooling, and supporting forcing properly align with sufficient snowfall rates materialize before temperatures diurnally rise, measurable snowfall still possible for the aforementioned locations, but this scenario is becoming less likely and primarily reserved for elevated surfaces. And snow-composed shower activity transitions to rain or melting snow by late morning, and into the afternoon period as flow orients NNW. This shifts most of the residual lake effect activity further east, favoring the eastern portions of Huron, Sanilac, and (northeastern) St. Clair Clair Counties. Temperatures should come in 5 to 10 F below normal, in the lower 40s, but with sustained winds of 10 to 15 mph, wind chills will start out in the 20s for a few locations. Some lake effect precipitation will exists along the same corridor overnight. A secondary upper low within the eastern flank of the blocking pattern will travel from north to south over the eastern half of the Great Lakes, in tandem with a similarly oriented mid-level speed max on Saturday. Lake-relevent trajectories should be more northwesterly at this time, which limits the viability of lake effect showers. The bulk of showers should again be limited to the St. Clair River vicinity. A couple degrees in thermal rebound could lift readings into the mid 40s Saturday, aided by weak warm advection. The longwave ridge begins to move eastward into the area Saturday night, with the downstream inflection point overhead Sunday. 1030 mb surface high pressure builds into southern Lower Michigan with time. The synoptic ridge then bisects the forecast area Monday as surface flow weakens and flips southwesterly as the center of the surface wave tracks into eastern Ohio. A warming trend is then forecast through next week as the ridge feature anchors over southern Appalachia with milder Gulf-modifed air lifting in. A progressive and deepening Pacific wave unblocks the configuration mid-week, but is expected to pivot over the Upper Midwest, likely keeping the local area dry through the forecast window. && .MARINE... Northerly flow will hold today before backing northwest through the weekend. This prolonged northerly flow will support efficient mixing of some stronger winds aloft down to the surface as cooler air remains in place. This will produce wind gusts around 25 knots along with elevated wave heights along the Lake Huron shoreline, where Small Craft Advisories remain in effect. Additionally, near surface convergence has supported lake effect rain bands across the central and southern Lake Huron basins, which will persist into tomorrow. Breezy conditions will start to wind down on Sunday once high pressure builds in over the southern Great Lakes. This will bring a period of lighter winds along with dry weather early next week. && .PREV DISCUSSION... Issued at 1209 AM EST Fri Nov 13 2026 AVIATION... A mix of MVFR and VFR ceilings scattered across the southeast Michigan as a robust lake effect response is getting underway. A south Lake Huron band is developing at the start of this TAF period with another dominant band forecast to develop off of Saginaw Bay later this morning. This puts FNT and DET with the higher likelihood to be most impacted downstream of these two

lake bands. It may be cold enough at FNT for a more prevailing snow p-type by this afternoon with DET warm enough for more of a mix of rain and snow. Lake clouds will maintain MVFR ceilings with pockets of IFR possible. There is potential for scattered rain/snow showers across other terminals as well. Shifting lower level winds towards the NW this evening will begin to direct lake bands east of the terminal corridor with some improvement in ceilings possible. For DTW... Lake effect response is getting underway across south Lake Huron. The more dominant band looks to set up closer towards DET. However, pieces of this activity could break off and reach DTW. This would be more focused late morning and early afternoon. Temperatures would be warm enough to support a rain-snow mix in this outcome with minimal if any accumulation. DTW THRESHOLD PROBABILITIES... * High for ceilings at or below 5,000 feet through this afternoon. * High for p-type as rain through much of tonight. Medium for rain- snow with any precip towards mid morning into the early afternoon. && .DTX WATCHES/ WARNINGS/ADVISORIES... MI...None. Lake Huron...Small Craft Advisory until 10 PM EST Saturday for LHZ421-422- 441>443. Lake St Clair...Small Craft Advisory until 4 AM EST early this morning for LCZ460. NWS PERIOD DETAIL

PERIOD	TEMP	DETAIL
Overnight	**30°F**	A chance of snow. Mostly cloudy. Low around 30, with temperatures rising to around 32 overnight. North northwest wind around 7 mph. Chance of precipitation is 30%. Little or no snow accumulation expected.
Friday	**42°F**	Snow likely before 8am, then rain and snow likely. Mostly cloudy. High near 42, with temperatures falling to around 40 in the afternoon. North northwest wind 7 to 12 mph, with gusts as high as 22 mph. Chance of precipitation is 70%. New snow accumulation of less than half an inch possible.
Friday Night	**27°F**	Mostly cloudy. Low around 27, with temperatures rising to around 30 overnight. Northwest wind around 8 mph, with gusts as high as 20 mph. New rainfall amounts less than a tenth of an inch possible.
Saturday	**43°F**	Mostly cloudy, with a high near 43. Northwest wind around 12 mph, with gusts as high as 23 mph.
Saturday Night	**30°F**	Mostly cloudy, with a low around 30. Northwest wind around 7 mph, with gusts as high as 18 mph.
Sunday	**44°F**	Partly sunny, with a high near 44.
Sunday Night	**26°F**	Partly cloudy, with a low around 26.
Monday	**47°F**	Sunny, with a high near 47.
Monday Night	**27°F**	Mostly clear, with a low around 27.
Tuesday	**51°F**	Sunny, with a high near 51.
Tuesday Night	**29°F**	Mostly clear, with a low around 29.
Wednesday	**54°F**	Sunny, with a high near 54.
Wednesday Night	**32°F**	Partly cloudy, with a low around 32.
Thursday	**56°F**	Partly sunny, with a high near 56.
